# TABLE OF CONTENTS

3 infrared satellite measurement of South America (sample of GOES 8 data)
4 excerpt of data corresponding to previous image
5 vertical profiles of Venus', Earth's, Mars', and Jupiter's atmospheres
6 vertical profile of Uranus' atmosphere
7 fractional composition of planetary atmospheres / a well-accepted model atmosphere for Earth
8 progress report written for honors committee (end of first semester)
9 page 1 of honors project report written for senior scholars presentation in early January
10 page 2
11 page 1 of program (std_atm.C) written for the project [variable and constant declaration]
12 page 2 [input initial parameters and user-defined constants]
13 page 3 [calculate values for troposphere, stratosphere, and mesosphere]
14 page 4 [calculate values for thermosphere / ask for extra calculations]
15 excerpts from output created by program (atmos.txt)
16 plot created from program's altitude and pressure output
17 actual plot of altitude vs. pressure
18 plot created from program's altitude and temperature output
19 actual plot of altitude vs. temperature
20 close-up of lowest 100km of atmosphere showing methods of heating and cooling
21 close-up of lowest 100km of atmosphere showing mixing rates
22 close-up of 150km-300km range of atmosphere showing solar influences on temperature
23 image showing the relative thickness of the atmosphere relative to the Earth [poorly reproduced]
24 image showing atmospheric data very well; cloud tops reaching to tropopause [poorly reproduced]
Fig. 1.14 Temperature profile of Venus' atmosphere. [This model is the NASA 1972 standard atmosphere, NASA Report S.P. 8081.]

Fig. 1.15 Schematic temperature profile for Earth's atmosphere showing the various regimes defined by the temperature gradient.

Fig. 1.16 Temperature profiles for Mars showing the effect of direct solar heating due to dust absorption. The shaded areas show the region of Mariner 6 and 7 observations. The curves at the left are calculated for a clear CO₂ atmosphere and at the right for one containing dust. [Calculations are due to Gerakaris and Goody (1972).]

Fig. 1.19 Schematic structure of the Jovian atmosphere. Even the adiabatic curve for the troposphere is uncertain, since it depends on the H₂/He mixture and the role of moist convection; also on low T; for H₂ is sensitive in T. Here we have taken a lapse rate of 20 K/km corresponding to γ = 1.6. The tropopause occurs at a minimum T of 100-120 K. A stratosphere is not shown because the profile is not known accurately enough for one to be sure that there is a temperature decrease above the tropopause. In the region just above the tropopause, T probably increases because of direct solar absorption, with a low level of infrared activity providing radiative cooling. At the mesopause, the main vibrational relaxation occurs in CH₃ and CH₄. In the thermosphere, curve (a) is the expected profile for heating by solar extreme ultraviolet and curve (b) is a profile inferred from the Pioneer 10 radio occultation. The discrepancy presumably indicates an additional heat source for the atmosphere.
ALTITUDE - PRESSURE - TEMPERATURE
Profile for Uranus

![Graph showing altitude, pressure, and temperature for Uranus with specific pressure levels marked: 3 mb, 10 mb, 30 mb, 100 mb, 300 mb, 1 bar, and 3 bar. The graph also highlights the tropopause.](image)

Planetary Atmospheric Dynamics
1st-Semester Summary

Progress

Past:

Read several books on Planetary Atmospheres, Fluid Dynamics, Atmospheric Physics, etc.

Researched valid sites from which I could get detailed text- and graphic-based GOES satellite data. Managed to get some useful data, but what was available did not seem very practical.

Found altitude-dependent graphical data on temperature, pressure, particle density, composition for Earth and even some for Mars, Venus, and Jupiter. Most is from 1978, but I’m currently searching to patch it up with more recent data.

Current:

Writing a program that will calculate a “standard atmosphere” for Earth. Fairly interactive... it asks for several input parameters for initial conditions. The program is dependent on the fact that Earth’s atmosphere is neatly stratified into distinct layers with distinct properties.

Looking for up-to-date data for Earth, Mars, and Venus regarding temperature and pressure profiles.

Constantly finding ways to increase the accuracy and portability (use on other bodies) of the standard atmosphere routine.

Future:

Get a working and accurate version of the program for Earth, Mars, and maybe Venus too (using up-to-date Magellan, Pathfinder, and MGS data for V and M). Once I’m certain I know what the tricks and obstacles are, I want to attempt to model Titan’s atmosphere. This will be interesting because details of it’s atmosphere are relatively unknown. The Cassini orbiter will :) drop the Huygens probe into Titan’s atmosphere (and surface?) in November 2004, then my model will truly be put to the test.

Depending on how long the program takes to ‘perfect’ for the various bodies, I would then like to look at atmospheric electrification. Lightning interests me a great deal and I think it would be fascinating to see what I can learn about how the process differs in different atmospheres with bizarre conditions.

If there is still time left, it probably means I came back for a fifth year!

Brian McNoldy
Planetary Atmospheric Dynamics

Astronomy and Physics Departmental Honors Project

-- Brian D. McNoldy --

This year-long honors project was inspired by an internship I held during the summer of 1997 at NASA's Goddard Space Flight Center. The topic of my research there was mesoscale properties of tropical convective systems. By analyzing radar and infrared satellite measurements, one can learn quite a bit about the relationship between cloud coverage and the underlying precipitation. Radar data is not very cheap or convenient to collect in most locations of the world (especially in oceanic regions); however, satellite data can be collected for any site in the world at least once a day. The amount of cloud coverage and rainfall over the tropical oceans greatly affects major weather patterns such as ENSO (El Niño Southern Oscillation).

Stepping back from the relatively specific focus of the internship, I began the honors project with the very general goal of learning about the planetary-scale structure and dynamics of various solar system bodies' (including Earth, Venus, Mars, and Saturn's moon Titan) atmospheres. Earth would serve as an excellent standard model because its structure is moderately well-understood and I could base computer model programming off of it. Venus was chosen because it has a very dense and uniform atmosphere. On the other hand, Mars has a sparse and more-layered atmosphere. Titan (the only moon known to have a substantial atmosphere) has never been studied experimentally, so modeling it will be a much greater challenge. The Cassini mission currently en route to the Saturnian system will drop a probe (Huygens) into Titan's nitrogen-rich atmosphere in November 2004; only then will my model truly be put to the test.

The computer model I have written is currently designed for Earth. It allows altitude-dependent calculations of pressure and temperature to be made, using user-defined parameters. At
the present time, my model matches reality up to about 20 km (tropopause) for pressure and up to
about 150 km (lower thermosphere) for temperature. My goal is to correctly model up to 1000 km
(thermosphere).

During the second half of the honors project (this semester), I plan to continue modeling the
temperature and pressure of Earth, Venus, Mars, and Titan. Depending on how long that takes, I
will then investigate atmospheric electrification. Lightning has been observed on Earth, Venus, and
Jupiter and almost certainly exists on Saturn and Titan. I would like to focus on the different
processes involved with electrification on each of the different bodies.

Useful Terms:

mesoscale- a weather feature that is defined to be 20-200 km in size and 12-36 hours in
duration.

convective- a weather system is said to be convective if its dynamics are driven by updrafts
and downdrafts due to warm/cool or moist/dry boundaries.

El Niño- a major oscillation in global atmospheric energy resulting in reversed wind flow
and increased temperatures in the equatorial Pacific Ocean. This in turn affects the
weather of most of North and South America.

troposphere- the lowest layer of our atmosphere. All weather occurs in this layer which
extends up to ~20 km above the surface of the Earth; the temperature
decreases with height.

tropopause- the boundary between the troposphere and the stratosphere. It occupies a thin
region at about 20 km above the surface.

stratosphere- the second layer of our atmosphere. Characterized by very little vertical air
movement. Exists between ~20-52 km and the temperature increases with
height.

stratopause- the boundary between the stratosphere and the mesosphere. It occupies a thin
region about 52 km above the surface.

mesosphere- the third distinctive layer of the atmosphere. It occupies the region between
52 km and 88 km. Temperature decreases with height once again.

mesopause- the boundary between the mesosphere and the thermosphere. It occupies the
region at about 88 km above the surface.

thermosphere- the next-to-last layer of the atmosphere. The rarefied air particles are
ionized by the constant bombardment of cosmic (X- and γ-) rays from
space. Due to this absorption and high atomic energies, temperatures in the
thermosphere climb with altitude, reaching as high as 2500°F during the
daytime. Extends from ~88-800 km.
